

# Package ‘htr2’

September 28, 2021

**Title** Perform HTTP Requests and Process the Responses

**Version** 0.1.1

**Description** Tools for creating and modifying HTTP requests, then performing them and processing the results. 'htr2' is a modern re-imagining of 'htr' that uses a pipe-based interface and solves more of the problems that API wrapping packages face.

**License** MIT + file LICENSE

**URL** <https://htr2.r-lib.org>, <https://github.com/r-lib/htr2>

**BugReports** <https://github.com/r-lib/htr2/issues>

**Depends** R (>= 3.4)

**Imports** cli (>= 3.0.0), curl, glue, magrittr, openssl, R6, rappdirs, rlang, withr

**Suggests** askpass, clipr, covr, docopt, httpuv, jose, jsonlite, knitr, purrr, rmarkdown, testthat (>= 3.0.0), tibble, webfakes, xml2

**VignetteBuilder** knitr

**Config/testthat/edition** 3

**Encoding** UTF-8

**RoxygenNote** 7.1.2

**NeedsCompilation** no

**Author** Hadley Wickham [aut, cre],  
RStudio [cph, fnd]

**Maintainer** Hadley Wickham <hadley@rstudio.com>

**Repository** CRAN

**Date/Publication** 2021-09-28 16:10:02 UTC

curl_translate	<i>Translate curl syntax to httr2</i>
----------------	---------------------------------------

---

### Description

The curl command line tool is commonly used to demonstrate HTTP APIs and can easily be generated from [browser developer tools](#). `curl_translate()` saves you the pain of manually translating these calls by implementing a partial, but frequently used, subset of curl options. Use `curl_help()` to see the supported options, and `curl_translate()` to translate a curl invocation copy and pasted from elsewhere.

Inspired by [curlconverter](#) written by [Bob Rudis](#).

### Usage

```
curl_translate(cmd)
```

```
curl_help()
```

### Arguments

cmd	Call to curl. If omitted and the clipr package is installed, will be retrieved from the clipboard.
-----	--

### Value

A string containing the translated httr2 code. If the input was copied from the clipboard, the translation will be copied back to the clipboard.

### Examples

```
curl_translate("curl http://example.com")
curl_translate("curl http://example.com -X DELETE")
curl_translate("curl http://example.com --header A:1 --header B:2")
curl_translate("curl http://example.com --verbose")
```

---

jwt_claim	<i>Create and encode a JWT</i>
-----------	--------------------------------

---

### Description

`jwt_claim()` is a wrapper around [jose::jwt\\_claim\(\)](#) that creates a JWT claim set with a few extra default values. `jwt_encode_sig()` and `jwt_encode_hmac()` are thin wrappers around [jose::jwt\\_encode\\_sig\(\)](#) and [jose::jwt\\_encode\\_hmac\(\)](#) that exist primarily to make specification in other functions a little simpler.

**Usage**

```

jwt_claim(
  iss = NULL,
  sub = NULL,
  aud = NULL,
  exp = unix_time() + 5L * 60L,
  nbf = unix_time(),
  iat = unix_time(),
  jti = NULL,
  ...
)

jwt_encode_sig(claim, key, size = 256, header = list())

jwt_encode_hmac(claim, secret, size = size, header = list())

```

**Arguments**

iss	Issuer claim. Identifies the principal that issued the JWT.
sub	Subject claim. Identifies the principal that is the subject of the JWT (i.e. the entity that the claims apply to).
aud	Audience claim. Identifies the recipients that the JWT is intended. Each principle intended to process the JWT must be identified with a unique value.
exp	Expiration claim. Identifies the expiration time on or after which the JWT MUST NOT be accepted for processing. Defaults to 5 minutes.
nbf	Not before claim. Identifies the time before which the JWT MUST NOT be accepted for processing. Defaults to current time.
iat	Issued at claim. Identifies the time at which the JWT was issued. Defaults to current time.
jti	JWT ID claim. Provides a unique identifier for the JWT. If omitted, uses a random 32-byte sequence encoded with base64url.
...	Any additional claims to include in the claim set.
claim	Claim set produced by <code>jwt_claim()</code> .
key	RSA or EC private key either specified as a path to a file, a connection, or a string (PEM/SSH format), or a raw vector (DER format).
size	Size, in bits, of sha2 signature, i.e. 256, 384 or 512. Only for HMAC/RSA, not applicable for ECDSA keys.
header	A named list giving additional fields to include in the JWT header.
secret	String or raw vector with a secret passphrase.

**Value**

An S3 list with class `jwt_claim`.

**Examples**

```
claim <- jwt_claim()
str(claim)
```

---

last_response	<i>Retrieve most recent request/response</i>
---------------	--

---

**Description**

These functions retrieve the most recent request made by htr2 and the response it received, to facilitate debugging problems *after* they occur. If the request did not succeed (or no requests have been made) last\_response() will be NULL.

**Usage**

```
last_response()
```

```
last_request()
```

**Value**

An HTTP [response/request](#).

**Examples**

```
invisible(request("http://htr2.r-lib.org") %>% req_perform())
last_request()
last_response()
```

---

multi_req_perform	<i>Perform multiple requests in parallel</i>
-------------------	--

---

**Description**

This variation on [req\\_perform\(\)](#) performs multiple requests in parallel. Unlike req\_perform() it always succeeds; it will never throw an error. Instead it will return error objects, which are your responsibility to handle.

Exercise caution when using this function; it's easy to pummel a server with many simultaneous requests. Only use it with hosts designed to serve many files at once.

**Usage**

```
multi_req_perform(reqs, paths = NULL, pool = NULL, cancel_on_error = FALSE)
```

**Arguments**

reqs	A list of <a href="#">requests</a> .
paths	An optional list of paths, if you want to download the request bodies to disks. If supplied, must be the same length as reqs.
pool	Optionally, a curl pool made by <a href="#">curl::new_pool()</a> . Supply this if you want to override the defaults for total concurrent connections (100) or concurrent connections per host (6).
cancel_on_error	Should all pending requests be cancelled when you hit an error. Set this to TRUE to stop all requests as soon as you hit an error. Responses that were never performed will have class <code>httr2_cancelled</code> in the result.

**Value**

A list the same length as reqs where each element is either a [response](#) or an error.

**Limitations**

- Will not retrieve a new OAuth token if it expires part way through the requests.
- Does not perform throttling with [req\\_throttle\(\)](#).
- Does not attempt retries as described by [req\\_retry\(\)](#).
- Consults the cache set by [req\\_cache\(\)](#) before/after all requests.

In general, where [req\\_perform\(\)](#) might make multiple requests due to retries or OAuth failures, [multi\\_req\\_perform\(\)](#) will make only make 1.

**Examples**

```
# Requesting these 4 pages one at a time would take four seconds:
reqs <- list(
  request("https://httpbin.org/delay/1"),
  request("https://httpbin.org/delay/1"),
  request("https://httpbin.org/delay/1"),
  request("https://httpbin.org/delay/1")
)
# But it's much faster if you request in parallel
system.time(resps <- multi_req_perform(reqs))

reqs <- list(
  request("https://httpbin.org/status/200"),
  request("https://httpbin.org/status/400"),
  request("FAILURE")
)
# multi_req_perform() will always succeed
resps <- multi_req_perform(reqs)
# you'll need to inspect the results to figure out which requests fails
fail <- vapply(resps, inherits, "error", FUN.VALUE = logical(1))
resps[fail]
```

---

`oauth_client`*Create an OAuth client*

---

### Description

An OAuth app is the combination of a client, a set of endpoints (i.e. urls where various requests should be sent), and an authentication mechanism. A client consists of at least a `client_id`, and also often a `client_secret`. You'll get these values when you create the client on the API's website.

### Usage

```
oauth_client(
    id,
    token_url,
    secret = NULL,
    key = NULL,
    auth = c("body", "header", "jwt_sig"),
    auth_params = list(),
    name = hash(id)
)
```

### Arguments

<code>id</code>	Client identifier.
<code>token_url</code>	Url to retrieve an access token.
<code>secret</code>	Client secret. For most apps, this is technically confidential so in principle you should avoid storing it in source code. However, many APIs require it in order to provide a user friendly authentication experience, and the risks of including it are usually low. To make things a little safer, I recommend using <a href="#">obfuscate()</a> when recorded the client secret in public code.
<code>key</code>	Client key. As an alternative to using a secret, you can instead supply a confidential private key. This should never be included in a package.
<code>auth</code>	Authentication mechanism used by the client to prove itself to the API. Can be one of three built-in methods ("body", "header", or "jwt"), or a function that will be called with arguments <code>req</code> , <code>client</code> , and the contents of <code>auth_params</code> . The most common mechanism in the wild is "body" where the <code>client_id</code> and (optionally) <code>client_secret</code> are added to the body. "header" sends in <code>client_id</code> and <code>client_secret</code> in HTTP Authorization header. "jwt_sig" will generate a JWT, and include it in a <code>client_assertion</code> field in the body. See <a href="#">oauth_client_req_auth()</a> for more details.
<code>auth_params</code>	Additional parameters passed to the function specified by <code>auth</code> .
<code>name</code>	Optional name for the client. Used when generating cache directory. If <code>NULL</code> , generated from hash of <code>client_id</code> . If you're defining a package for use in a package, I recommend that you use the package name.

**Value**

An OAuth client: An S3 list with class `httr2_oauth_client`.

**Examples**

```
oauth_client("myclient", "http://example.com/token_url", secret = "DONTLOOK")
```

---

`oauth_client_req_auth` *OAuth client authentication*

---

**Description**

`oauth_client_req_auth()` authenticates a request using the authentication strategy defined by the `auth` and `auth_param` arguments to `oauth_client()`. This used to authenticate the client as part of the OAuth flow, **not** to authenticate a request on behalf of a user.

There are three built-in strategies:

- `oauth_client_req_body()` adds the client id and (optionally) the secret to the request body, as described in [rfc6749](#), Section 2.3.1.
- `oauth_client_req_header()` adds the client id and secret using HTTP basic authentication with the Authorization header, as described in [rfc6749](#), Section 2.3.1.
- `oauth_client_jwt_rs256()` adds a client assertion to the body using a JWT signed with `jwt_sign_rs256()` using a private key, as described in [rfc7523](#), Section 2.2.

You will generally not call these functions directly but will instead specify them through the `auth` argument to `oauth_client()`. The `req` and `client` parameters are automatically filled in; other parameters come from the `auth_params` argument.

**Usage**

```
oauth_client_req_auth(req, client)
```

```
oauth_client_req_auth_header(req, client)
```

```
oauth_client_req_auth_body(req, client)
```

```
oauth_client_req_auth_jwt_sig(req, client, claim, size = 256, header = list())
```

**Arguments**

<code>req</code>	A <a href="#">request</a> .
<code>client</code>	An <a href="#">oauth_client</a> .
<code>claim</code>	Claim set produced by <a href="#">jwt_claim()</a> .
<code>size</code>	Size, in bits, of sha2 signature, i.e. 256, 384 or 512. Only for HMAC/RSA, not applicable for ECDSA keys.
<code>header</code>	A named list giving additional fields to include in the JWT header.

**Value**

A modified HTTP [request](#).

**Examples**

```
# Show what the various forms of client authentication look like
req <- request("https://example.com/whoami")
```

```
client1 <- oauth_client(
  id = "12345",
  secret = "56789",
  token_url = "https://example.com/oauth/access_token",
  name = "oauth-example",
  auth = "body" # the default
)
# calls oauth_client_req_auth_body()
req_dry_run(oauth_client_req_auth(req, client1))
```

```
client2 <- oauth_client(
  id = "12345",
  secret = "56789",
  token_url = "https://example.com/oauth/access_token",
  name = "oauth-example",
  auth = "header"
)
# calls oauth_client_req_auth_header()
req_dry_run(oauth_client_req_auth(req, client2))
```

```
client3 <- oauth_client(
  id = "12345",
  key = openssl::rsa_keygen(),
  token_url = "https://example.com/oauth/access_token",
  name = "oauth-example",
  auth = "jwt_sig",
  auth_params = list(claim = jwt_claim())
)
# calls oauth_client_req_auth_header_jwt_sig()
req_dry_run(oauth_client_req_auth(req, client3))
```

---

oauth\_token

*Create an OAuth token*

---

**Description**

Creates a S3 object of class `<httr2_token>` representing an OAuth token returned from the access token endpoint.

**Usage**

```
oauth_token(
  access_token,
  token_type = "bearer",
  expires_in = NULL,
  refresh_token = NULL,
  ...,
  .date = Sys.time()
)
```

**Arguments**

<code>access_token</code>	The access token used to authenticate request
<code>token_type</code>	Type of token; only "bearer" is currently supported.
<code>expires_in</code>	Number of seconds until token expires.
<code>refresh_token</code>	Optional refresh token; if supplied, this can be used to cheaply get a new access token when this one expires.
<code>...</code>	Additional components returned by the endpoint
<code>.date</code>	Date the request was made; used to convert the relative <code>expires_in</code> to an absolute <code>expires_at</code> .

**Value**

An OAuth token: an S3 list with class `httr2_token`.

**Examples**

```
oauth_token("abcdef")
oauth_token("abcdef", expires_in = Sys.time() + 3600)
oauth_token("abcdef", refresh_token = "ghijkl")
```

---

obfuscate

*Obfuscate mildly secret information*

---

**Description**

This pair of functions provides a way to obfuscate mildly confidential information, like OAuth client secrets. The secret can not be revealed from your source code, but a good R programmer could still figure it out with a little effort. The main goal is to protect against scraping; there's no way for an automated tool to grab your obfuscated secrets.

Because un-obfuscation happens at the last possible instant, `obfuscated()` only works in limited locations:

- The secret argument to `oauth_client()`
- Elements of the data argument to `req_body_form()`, `req_body_json()`, and `req_body_multipart()`.

**Usage**

```
obfuscate(x)
```

```
obfuscated(x)
```

**Arguments**

x                    A string to obfuscate, or mark as obfuscated.

**Value**

obfuscate() prints the obfuscated() call to include in your code. obfuscated() returns an S3 class marking the string as obfuscated so it can be unobfuscated when needed.

**Examples**

```
obfuscate("good morning")

# Every time you obfuscate you'll get a different value because it
# includes 16 bytes of random data which protects against certain types of
# brute force attack
obfuscate("good morning")
```

---

request	<i>Create a new HTTP request</i>
---------	----------------------------------

---

**Description**

To perform a HTTP request, first create a request object with `request()`, then define its behaviour with `req_` functions, then perform the request and fetch the response with `req_perform()`.

**Usage**

```
request(base_url)
```

**Arguments**

base\_url            Base URL for request.

**Value**

An HTTP response: an S3 list with class `httr2_request`.

**Examples**

```
request("http://r-project.org")
```

---

req_auth_basic	<i>Authenticate request with HTTP basic authentication</i>
----------------	--

---

## Description

This sets the Authorization header. See details at <https://developer.mozilla.org/en-US/docs/Web/HTTP/Headers/Authorization>.

## Usage

```
req_auth_basic(req, username, password = NULL)
```

## Arguments

req	A <a href="#">request</a> .
username	User name.
password	Password. You avoid entering the password directly when calling this function as it will be captured by <code>.Rhistory</code> . Instead, leave it unset and the default behaviour will prompt you for it interactively.

## Value

A modified HTTP [request](#).

## Examples

```
req <- request("http://example.com") %>% req_auth_basic("hadley", "SECRET")
req
req %>% req_dry_run()

# httr2 does its best to redact the Authorization header so that you don't
# accidentally reveal confidential data. Use `redact_headers` to reveal it:
print(req, redact_headers = FALSE)
req %>% req_dry_run(redact_headers = FALSE)

# We do this because the authorization header is not encrypted and the
# so password can easily be discovered:
rawToChar(jsonlite::base64_dec("aGFkbGV5O1NFQ1JFVA=="))
```

---

req\_auth\_bearer\_token *Authenticate request with bearer token*

---

### Description

A bearer token gives the bearer access to confidential resources (so you should keep them secure like you would with a user name and password). They are usually produced by some large authentication scheme (like the various OAuth 2.0 flows), but you are sometimes given them directly.

### Usage

```
req_auth_bearer_token(req, token)
```

### Arguments

req	A <a href="#">request</a> .
token	A bearer token

### Value

A modified HTTP [request](#).

### See Also

[RFC750](#) The OAuth 2.0 Authorization Framework: Bearer Token Usage

### Examples

```
req <- request("http://example.com") %>% req_auth_bearer_token("sda1jsdf0931kfs")
req

# httr2 does its best to redact the Authorization header so that you don't
# accidentally reveal confidential data. Use `redact_headers` to reveal it:
print(req, redact_headers = FALSE)
```

---

req\_body *Send data in request body*

---

### Description

- req\_body\_file() sends a local file.
- req\_body\_raw() sends a string or raw vector.
- req\_body\_json() sends JSON encoded data.
- req\_body\_form() sends form encoded data.
- req\_body\_multipart() creates a multi-part body.

Adding a body to a request will automatically switch the method to POST.

**Usage**

```
req_body_raw(req, body, type = NULL)

req_body_file(req, path, type = NULL)

req_body_json(req, data, auto_unbox = TRUE, digits = 22, null = "null", ...)

req_body_form(req, data)

req_body_multipart(req, data)
```

**Arguments**

req	A <a href="#">request</a> .
body	A literal string or raw vector to send as body.
type	Content type. For <code>req_body_file()</code> , the default will attempt to guess from the extension of path.
path	Path to file to upload.
data	Data to include in body. For <code>req_body_json()</code> this can be any R data structure that can be serialised to JSON, for <code>req_body_form()</code> it should be a named list of simple values, and <code>req_body_multipart()</code> it should be a named list containing strings or objects produced by <code>curl::form_file()/curl::form_data()</code> .
auto_unbox	Should length-1 vectors be automatically "unboxed" to JSON scalars?
digits	How many digits of precision should numbers use in JSON?
null	Should NULL be translated to JSON's null ("null") or an empty list ("list").
...	Other arguments passed on to <code>jsonlite::toJSON()</code> .

**Value**

A modified HTTP [request](#).

**Examples**

```
req <- request("http://httpbin.org/post")

# Most APIs expect small amounts of data in either form or json encoded:
req %>%
  req_body_form(list(x = "A simple text string")) %>%
  req_dry_run()

req %>%
  req_body_json(list(x = "A simple text string")) %>%
  req_dry_run()

# For total control over the body, send a string or raw vector
req %>%
  req_body_raw("A simple text string") %>%
```

```

req_dry_run()

# There are two main ways that APIs expect entire files
path <- tempfile()
writeLines(letters[1:6], path)

# You can send a single file as the body:
req %>%
  req_body_file(path) %>%
  req_dry_run()

# You can send multiple files, or a mix of files and data
# with multipart encoding
req %>%
  req_body_multipart(list(a = curl::form_file(path), b = "some data")) %>%
  req_dry_run()

```

---

req\_cache

*Automatically cache requests*

---

## Description

Use `req_perform()` to automatically cache HTTP requests. Most API requests are not cacheable, but static files often are.

`req_cache()` caches responses to GET requests that have status code 200 and at least one of the standard caching headers (e.g. Expires, Etag, Last-Modified, Cache-Control), unless caching has been expressly prohibited with Cache-Control: no-store. Typically, a request will still be sent to the server to check that the cached value is still up-to-date, but it will not need to re-download the body value.

To learn more about HTTP caching, I recommend the MDN article [HTTP caching](#).

## Usage

```
req_cache(req, path, use_on_error = FALSE, debug = FALSE)
```

## Arguments

<code>req</code>	A <a href="#">request</a> .
<code>path</code>	Path to cache directory
<code>use_on_error</code>	If the request errors, and there's a cache response, should <code>req_perform()</code> return that instead of generating an error?
<code>debug</code>	When TRUE will emit useful messages telling you about cache hits and misses. This can be helpful to understand whether or not caching is actually doing anything for your use case.

## Value

A modified HTTP [request](#).

**Examples**

```
# GitHub uses HTTP caching for all raw files.
url <- paste0(
  "https://raw.githubusercontent.com/allisonhorst/palmerpenguins/",
  "master/inst/extdata/penguins.csv"
)
# Here I set debug = TRUE so you can see what's happening
req <- request(url) %>% req_cache(tempdir(), debug = TRUE)

# First request downloads the data
resp <- req %>% req_perform()

# Second request retrieves it from the cache
resp <- req %>% req_perform()
```

---

req\_dry\_run

*Perform a dry run*

---

**Description**

This shows you exactly what httr2 will send to the server, without actually sending anything. It requires the httpuv package because it works by sending the real HTTP request to a local webserver, thanks to the magic of `curl::curl_echo()`.

**Usage**

```
req_dry_run(req, quiet = FALSE, redact_headers = TRUE)
```

**Arguments**

req	A <a href="#">request</a> .
quiet	If TRUE doesn't print anything.
redact_headers	Redact confidential data in the headers? Currently redacts the contents of the Authorization header to prevent you from accidentally leaking credentials when debugging/repexing.

**Value**

Invisibly, a list containing information about the request, including method, path, and headers.

**Examples**

```
# httr2 adds default User-Agent, Accept, and Accept-Encoding headers
request("http://example.com") %>% req_dry_run()

# the Authorization header is automatically redacted to avoid leaking
# credentials on the console
req <- request("http://example.com") %>% req_auth_basic("user", "password")
```

```
req %>% req_dry_run()

# if you need to see it, use redact_headers = FALSE
req %>% req_dry_run(redact_headers = FALSE)
```

---

req\_error *Control handling of HTTP errors*

---

## Description

`req_perform()` will automatically convert HTTP errors (i.e. any 4xx or 5xx status code) into R errors. Use `req_perform()` to either override the defaults, or extract additional information from the response that would be useful to expose to the user.

## Usage

```
req_error(req, is_error = NULL, body = NULL)
```

## Arguments

<code>req</code>	A <a href="#">request</a> .
<code>is_error</code>	A predicate function that takes a single argument (the response) and returns TRUE or FALSE indicating whether or not an R error should signalled.
<code>body</code>	A callback function that takes a single argument (the response) and returns a character vector of additional information to include in the body of the error. This vector is passed along to the message argument of <a href="#">rlang::abort()</a> so you can use any formatting that it supports.

## Value

A modified HTTP [request](#).

## See Also

[req\\_retry\(\)](#) to control when errors are automatically retried.

## Examples

```
# Performing this request usually generates an error because httr2
# converts HTTP errors into R errors:
req <- request("http://httpbin.org/404")
try(req %>% req_perform())
# You can still retrieve it with last_response()
last_response()

# But you might want to suppress this behaviour:
resp <- req %>%
  req_error(is_error = function(resp) FALSE) %>%
```

```

    req_perform()
  resp

  # Or perhaps you're working with a server that routinely uses the
  # wrong HTTP error codes only 500s are really errors
  request("http://example.com") %>%
    req_error(is_error = function(resp) resp_status(resp) == 500)

  # Most typically you'll use req_error() to add additional information
  # extracted from the response body (or sometimes header):
  error_body <- function(resp) {
    resp_body_json(resp)$error
  }
  request("http://example.com") %>%
    req_error(body = error_body)
  # Learn more in vignette("wrapping-apis")

```

---

req\_headers

*Modify request headers*

---

## Description

req\_headers() allows you to set the value of any header.

## Usage

```
req_headers(.req, ...)
```

## Arguments

.req	A <a href="#">request</a> .
...	Name-value pairs of headers and their values. <ul style="list-style-type: none"> <li>• Use NULL to reset a value to httr's default</li> <li>• Use "" to remove a header</li> <li>• Use a character vector to repeat a header.</li> </ul>

## Value

A modified HTTP [request](#).

## Examples

```

req <- request("http://example.com")

# Use req_headers() to add arbitrary additional headers to the request
req %>%
  req_headers(MyHeader = "MyValue") %>%
  req_dry_run()

```

```

# Repeated use overrides the previous value:
req %>%
  req_headers(MyHeader = "Old value") %>%
  req_headers(MyHeader = "New value") %>%
  req_dry_run()

# Setting Accept to NULL uses curl's default:
req %>%
  req_headers(Accept = NULL) %>%
  req_dry_run()

# Setting it to "" removes it:
req %>%
  req_headers(Accept = "") %>%
  req_dry_run()

# If you need to repeat a header, provide a vector of values
# (this is rarely needed, but is important in a handful of cases)
req %>%
  req_headers(HeaderName = c("Value 1", "Value 2", "Value 3")) %>%
  req_dry_run()

```

---

req_method	<i>Set HTTP method in request</i>
------------	-----------------------------------

---

## Description

Use this function to use a custom HTTP method like "HEAD", "DELETE", "PATCH", "UPDATE", or "OPTIONS".

## Usage

```
req_method(req, method)
```

## Arguments

req	A <a href="#">request</a> .
method	Custom HTTP method

## Value

A modified HTTP [request](#).

## Examples

```

request("http://httpbin.org") %>% req_method("PATCH")
request("http://httpbin.org") %>% req_method("PUT")
request("http://httpbin.org") %>% req_method("HEAD")

```

---

req\_oauth\_auth\_code     *OAuth authentication with authorization code*

---

### Description

This uses `oauth_flow_auth_code()` to generate an access token, which is then used to authentication the request with `req_auth_bearer_token()`. The token is automatically cached (either in memory or on disk) to minimise the number of times the flow is performed.

### Usage

```
req_oauth_auth_code(
  req,
  client,
  auth_url,
  cache_disk = FALSE,
  cache_key = NULL,
  scope = NULL,
  pkce = TRUE,
  auth_params = list(),
  token_params = list(),
  host_name = "localhost",
  host_ip = "127.0.0.1",
  port = httpuv::randomPort()
)
```

### Arguments

<code>req</code>	A <a href="#">request</a> .
<code>client</code>	An <a href="#">oauth_client()</a> .
<code>auth_url</code>	Authorization url; you'll need to discover this by reading the documentation.
<code>cache_disk</code>	Should the access token be cached on disk? This reduces the number of times that you need to re-authenticate at the cost of storing access credentials on disk. Cached tokens are encrypted and automatically deleted 30 days after creation.
<code>cache_key</code>	If you want to cache multiple tokens per app, use this key to disambiguate them.
<code>scope</code>	Scopes to be requested from the resource owner.
<code>pkce</code>	Use "Proof Key for Code Exchange"? This adds an extra layer of security and should always be used if supported by the server.
<code>auth_params</code>	List containing additional parameters passed to <code>oauth_flow_auth_code_url()</code>
<code>token_params</code>	List containing additional parameters passed to the <code>token_url</code> .
<code>host_name</code>	Host name used to generate <code>redirect_uri</code>
<code>host_ip</code>	IP address web server will be bound to.
<code>port</code>	Port to bind web server to. By default, this uses a random port. You may need to set it to a fixed port if the API requires that the <code>redirect_uri</code> specified in the client exactly matches the <code>redirect_uri</code> generated by this function.

**Value**

A modified HTTP [request](#).

**Security considerations**

The authorization code flow is used for both web applications and native applications (which are equivalent to R packages). [rfc8252](#) spells out important considerations for native apps. Most importantly there's no way for native apps to keep secrets from their users. This means that the server should either not require a `client_secret` (i.e. a public client not an confidential client) or ensure that possession of the `client_secret` doesn't bestow any meaningful rights.

Only modern APIs from the bigger players (Azure, Google, etc) explicitly native apps. However, in most cases, even for older APIs, possessing the `client_secret` gives you no ability to do anything harmful, so our general principle is that it's fine to include it in an R package, as long as it's mildly obfuscated to protect it from credential scraping. There's no incentive to steal your client credentials if it takes less time to create a new client than find your client secret.

**Examples**

```
client <- oauth_client(
  id = "28acfec0674bb3da9f38",
  secret = obfuscated(paste0(
    "J9iiGmyelHltyxqrHXW41ZZPZamyUNxSX1_uKnv",
    "PeinhxET_7FfUs2X0LLKotXY2bpgOMoHRCo"
  )),
  token_url = "https://github.com/login/oauth/access_token",
  name = "hadley-oauth-test"
)

request("https://api.github.com/user") %>%
  req_oauth_auth_code(client, auth_url = "https://github.com/login/oauth/authorize")
```

---

req\_oauth\_bearer\_jwt    *OAuth authentication with a bearer JWT*

---

**Description**

This uses [oauth\\_flow\\_bearer\\_jwt\(\)](#) to generate an access token which is then used to authenticate the request with [req\\_auth\\_bearer\\_token\(\)](#). The token is cached in memory.

**Usage**

```
req_oauth_bearer_jwt(
  req,
  client,
  claim,
  signature = "jwt_encode_sig",
  signature_params = list(),
```

```

    scope = NULL,
    token_params = list()
  )

```

### Arguments

req	A <a href="#">request</a> .
client	An <a href="#">oauth_client()</a> .
claim	A list of claims. If all elements of the claim set are static apart from iat, nbf, exp, or jti, provide a list and <a href="#">jwt_claim()</a> will automatically fill in the dynamic components. If other components need to vary, you can instead provide a zero-argument callback function which should call <a href="#">jwt_claim()</a> .
signature	Function use to sign claim, e.g. <a href="#">jwt_encode_sig()</a> .
signature_params	Additional arguments passed to signature, e.g. size, header.
scope	Scopes to be requested from the resource owner.
token_params	List containing additional parameters passed to the token_url.

### Value

A modified HTTP [request](#).

### Examples

```

client <- oauth_client("example", "https://example.com/get_token")
claim <- jwt_claim()
req <- request("https://example.com")

req %>% req_oauth_bearer_jwt(client, claim)

```

---

req\_oauth\_client\_credentials

*OAuth authentication with client credentials*

---

### Description

This uses [oauth\\_flow\\_client\\_credentials\(\)](#) to generate an access token, which is then used to authentication the request with [req\\_auth\\_bearer\\_token\(\)](#). The token is cached in memory.

### Usage

```
req_oauth_client_credentials(req, client, scope = NULL, token_params = list())
```

**Arguments**

req	A <a href="#">request</a> .
client	An <a href="#">oauth_client()</a> .
scope	Scopes to be requested from the resource owner.
token_params	List containing additional parameters passed to the token_url.

**Value**

A modified HTTP [request](#).

**Examples**

```
client <- oauth_client("example", "https://example.com/get_token")
req <- request("https://example.com")

req %>% req_oauth_client_credentials(client)
```

---

req_oauth_device	<i>OAuth authentication with device flow</i>
------------------	--

---

**Description**

This uses [oauth\\_flow\\_device\(\)](#) to generate an access token, which is then used to authentication the request with [req\\_auth\\_bearer\\_token\(\)](#). The token is automatically cached (either in memory or on disk) to minimise the number of times the flow is performed.

**Usage**

```
req_oauth_device(
  req,
  client,
  cache_disk = FALSE,
  cache_key = NULL,
  scope = NULL,
  auth_params = list(),
  token_params = list()
)
```

**Arguments**

req	A <a href="#">request</a> .
client	An <a href="#">oauth_client()</a> .
cache_disk	Should the access token be cached on disk? This reduces the number of times that you need to re-authenticate at the cost of storing access credentials on disk. Cached tokens are encrypted and automatically deleted 30 days after creation.

cache_key	If you want to cache multiple tokens per app, use this key to disambiguate them.
scope	Scopes to be requested from the resource owner.
auth_params	List containing additional parameters passed to <code>oauth_flow_auth_code_url()</code>
token_params	List containing additional parameters passed to the <code>token_url</code> .

**Value**

A modified HTTP [request](#).

**Examples**

```
client <- oauth_client("example", "https://example.com/get_token")
req <- request("https://example.com")

req %>% req_oauth_device(client)
```

---

req\_oauth\_password      *OAuth authentication with username and password*

---

**Description**

This uses `oauth_flow_password()` to generate an access token, which is then used to authentication the request with `req_auth_bearer_token()`. The token, not the password is automatically cached (either in memory or on disk); the password is used once to get the token and is then discarded.

**Usage**

```
req_oauth_password(
  req,
  client,
  username,
  password = NULL,
  cache_disk = FALSE,
  scope = NULL,
  token_params = list()
)
```

**Arguments**

req	A <a href="#">request</a> .
client	An <code>oauth_client()</code> .
username	User name.
password	Password. You avoid entering the password directly when calling this function as it will be captured by <code>.Rhistory</code> . Instead, leave it unset and the default behaviour will prompt you for it interactively.

cache_disk	Should the access token be cached on disk? This reduces the number of times that you need to re-authenticate at the cost of storing access credentials on disk. Cached tokens are encrypted and automatically deleted 30 days after creation.
scope	Scopes to be requested from the resource owner.
token_params	List containing additional parameters passed to the token_url.

**Value**

A modified HTTP [request](#).

**Examples**

```
client <- oauth_client("example", "https://example.com/get_token")
req <- request("https://example.com")

if (interactive()) {
  req %>% req_oauth_password(client, "username")
}
```

---

req\_oauth\_refresh      *OAuth authentication with a refresh token*

---

**Description**

This uses [oauth\\_flow\\_refresh\(\)](#) to generate an access token, which is then used to authentication the request with [req\\_auth\\_bearer\\_token\(\)](#). This is primarily useful for testing: you can manually execute another OAuth flow (e.g. by calling [oauth\\_flow\\_auth\\_code\(\)](#) or [oauth\\_flow\\_device\(\)](#)), extract the refresh token from the result, and then save in an environment variable for future use in automated tests.

When requesting an access token, the server may also return a new refresh token. If this happens, [oauth\\_flow\\_refresh\(\)](#) will error, and you'll have to create a new refresh token following the same procedure you did to get the first token (so it's a good idea to document what you did the first time because you might need to do it again).

**Usage**

```
req_oauth_refresh(
  req,
  client,
  refresh_token = Sys.getenv("HTTR_REFRESH_TOKEN"),
  scope = NULL,
  token_params = list()
)
```

**Arguments**

req	A <a href="#">request</a> .
client	An <a href="#">oauth_client()</a> .
refresh_token	A refresh token. This is equivalent to a password so shouldn't be typed into the console or stored in a script. Instead, we recommend placing in an environment variable; the default behaviour is to look in HTR_REFRESH_TOKEN.
scope	Scopes to be requested from the resource owner.
token_params	List containing additional parameters passed to the token_url.

**Value**

A modified HTTP [request](#).

**Examples**

```
client <- oauth_client("example", "https://example.com/get_token")
req <- request("https://example.com")
req %>% req_oauth_refresh(client)
```

---

req_perform	<i>Perform a request</i>
-------------	--------------------------

---

**Description**

After preparing a [request](#), call `req_perform()` to perform it, fetching the results back to R as a [response](#).

**Usage**

```
req_perform(
  req,
  path = NULL,
  verbosity = getOption("httr2_verbosity", 0L),
  mock = getOption("httr2_mock", NULL)
)
```

**Arguments**

req	A <a href="#">request</a> .
path	Optionally, path to save body of request. This is useful for large responses since it avoids storing the response in memory.
verbosity	How much information to print? This is a wrapper around <code>req_verbosity()</code> that uses an integer to control verbosity: <ul style="list-style-type: none"> <li>• 0: no output</li> <li>• 1: show headers</li> </ul>

- 2: show headers and bodies
  - 3: show headers, bodies, and curl status messages.
- mock A mocking function. If supplied, this function is called with the request. It should return either NULL (if it doesn't want to handle the request) or a [response](#) (if it does). See [with\\_mock\(\)](#)/[local\\_mock\(\)](#) for more details.

## Value

If request is successful (i.e. the request was successfully performed and a response with HTTP status code <400 was received), an HTTP [response](#); otherwise throws an error. Override this behaviour with [req\\_error\(\)](#).

## Requests

Note that one call to [req\\_perform\(\)](#) may perform multiple HTTP requests:

- If the url is redirected with a 301, 302, 303, or 307, curl will automatically follow the Location header to the new location.
- If you have configured retries with [req\\_retry\(\)](#) and the request fails with a transient problem, [req\\_perform\(\)](#) will try again after waiting a bit. See [req\\_retry\(\)](#) for details.
- If you are using OAuth, and the cached token has expired, [req\\_perform\(\)](#) will get a new token either using the refresh token (if available) or by running the OAuth flow.

## Examples

```
request("https://google.com") %>%
  req_perform()
```

---

<code>req_retry</code>	<i>Control when a request will retry, and how long it will wait between tries</i>
------------------------	---

---

## Description

[req\\_retry\(\)](#) alters [req\\_perform\(\)](#) so that it will automatically retry in the case of failure. To activate it, you must specify either the total number of requests to make with `max_tries` or the total amount of time to spend with `max_seconds`. Then [req\\_perform\(\)](#) will retry if:

- The either the HTTP request or HTTP response doesn't complete successfully leading to an error from curl, the lower-level library that htr uses to perform HTTP request. This occurs, for example, if your wifi is down.
- The error is "transient", i.e. it's an HTTP error that can be resolved by waiting. By default, 429 and 503 statuses are treated as transient, but if the API you are wrapping has other transient status codes (or conveys transient-ness with some other property of the response), you can override the default with `is_transient`.

It's a bad idea to immediately retry a request, so [req\\_perform\(\)](#) will wait a little before trying again:

- If the response contains the `Retry-After` header, `httr2` will wait the amount of time it specifies. If the API you are wrapping conveys this information with a different header (or other property of the response) you can override the default behaviour with `retry_after`.
- Otherwise, `httr2` will use "truncated exponential backoff with full jitter", i.e. it will wait a random amount of time between one second and  $2^{\text{tries}}$  seconds, capped to at most 60 seconds. In other words, it waits `runif(1, 1, 2)` seconds after the first failure, `runif(1, 1, 4)` after the second, `runif(1, 1, 8)` after the third, and so on. If you'd prefer a different strategy, you can override the default with `backoff`.

## Usage

```
req_retry(
  req,
  max_tries = NULL,
  max_seconds = NULL,
  is_transient = NULL,
  backoff = NULL,
  after = NULL
)
```

## Arguments

<code>req</code>	A <a href="#">request</a> .
<code>max_tries</code> , <code>max_seconds</code>	Cap the maximum number of attempts with <code>max_tries</code> or the total elapsed time from the first request with <code>max_seconds</code> . If neither option is supplied (the default), <code>req_perform()</code> will not retry.
<code>is_transient</code>	A predicate function that takes a single argument (the response) and returns <code>TRUE</code> or <code>FALSE</code> specifying whether or not the response represents a transient error.
<code>backoff</code>	A function that takes a single argument (the number of failed attempts so far) and returns the number of seconds to wait.
<code>after</code>	A function that takes a single argument (the response) and returns either a number of seconds to wait or <code>NULL</code> , which indicates that a precise wait time is not available that the backoff strategy should be used instead.

## Value

A modified HTTP [request](#).

## See Also

[req\\_throttle\(\)](#) if the API has a rate-limit but doesn't expose the limits in the response.

## Examples

```
# google APIs assume that a 500 is also a transient error
request("http://google.com") %>%
  req_retry(is_transient = ~ resp_status(.x) %in% c(429, 500, 503))
```

```

# use a constant 10s delay after every failure
request("http://example.com") %>%
  req_retry(backoff = ~ 10)

# When rate-limited, GitHub's API returns a 403 with
# `X-RateLimit-Remaining: 0` and an Unix time stored in the
# `X-RateLimit-Reset` header. This takes a bit more work to handle:
github_is_transient <- function(resp) {
  resp_status(resp) == 403 &&
  identical(resp_header(resp, "X-RateLimit-Remaining"), "0")
}
github_after <- function(resp) {
  time <- as.numeric(resp_header(resp, "X-RateLimit-Reset"))
  time - unclass(Sys.time())
}
request("http://api.github.com") %>%
  req_retry(
    is_transient = github_is_transient,
    after = github_after
  )

```

---

req\_stream

*Perform a request, streaming data back to R*

---

## Description

After preparing a request, call `req_stream()` to perform the request and handle the result with a streaming callback. This is useful for streaming HTTP APIs where potentially the stream never ends.

## Usage

```
req_stream(req, callback, timeout_sec = Inf, buffer_kb = 64)
```

## Arguments

<code>req</code>	A <a href="#">request</a> .
<code>callback</code>	A single argument callback function. It will be called repeatedly with a raw vector whenever there is at least <code>buffer_kb</code> worth of data to process. It must return TRUE to continue streaming.
<code>timeout_sec</code>	Number of seconds to process stream for.
<code>buffer_kb</code>	Buffer size, in kilobytes.

## Value

An HTTP [response](#).

**Examples**

```
show_bytes <- function(x) {
  cat("Got ", length(x), " bytes\n", sep = "")
  TRUE
}
resp <- request("http://httpbin.org/stream-bytes/100000") %>%
  req_stream(show_bytes, buffer_kb = 32)
```

---

req\_template

*Set request method/path from a template*

---

**Description**

Many APIs document their methods with a lightweight template mechanism that looks like GET /user/{user} or POST /organisation/:org. This function makes it easy to copy and paste this snippets and retrieve template variables either from function arguments or the current environment:

**Usage**

```
req_template(req, template, ..., .env = parent.frame())
```

**Arguments**

req	A <a href="#">request</a> .
template	A template string which consists of a optional HTTP method and a path containing variables labelled like either :foo or {foo}.
...	Template variables.
.env	Environment in which to look for template variables not found in .... Expert use only.

**Value**

A modified HTTP [request](#).

**Examples**

```
httpbin <- request("http://httpbin.org")

# You can supply template parameters in `...`
httpbin %>% req_template("GET /bytes/{n}", n = 100)

# or you retrieve from the current environment
n <- 200
httpbin %>% req_template("GET /bytes/{n}")
```

---

req_throttle	<i>Throttle a request by automatically adding a delay</i>
--------------	---

---

**Description**

Use `req_throttle()` to ensure that repeated calls to `req_perform()` never exceed a specified rate.

**Usage**

```
req_throttle(req, rate, realm = NULL)
```

**Arguments**

<code>req</code>	A <a href="#">request</a> .
<code>rate</code>	Maximum rate, i.e. maximum number of requests per second. Usually easiest expressed as a fraction, <code>number_of_requests / number_of_seconds</code> , e.g. 15 requests per minute is <code>15 / 60</code> .
<code>realm</code>	An unique identifier that for throttle pool. If not supplied, defaults to the host-name of the request.

**Value**

A modified HTTP [request](#).

**See Also**

[req\\_retry\(\)](#) for another way of handling rate-limited APIs.

**Examples**

```
# Ensure server will never receive more than 10 requests a minute
request("https://example.com") %>%
  req_throttle(rate = 10 / 60)
```

---

req_timeout	<i>Set time limit for a request</i>
-------------	-------------------------------------

---

**Description**

An error will be thrown if the request does not complete in the time limit.

**Usage**

```
req_timeout(req, seconds)
```

**Arguments**

req	A <a href="#">request</a> .
seconds	Maximum number of seconds to wait

**Value**

A modified HTTP [request](#).

**Examples**

```
# Give up after at most 10 seconds
request("http://example.com") %>% req_timeout(10)
```

---

req_url	<i>Modify request URL</i>
---------	---------------------------

---

**Description**

- req\_url() replaces the entire url
- req\_url\_query() modifies the components of the query
- req\_url\_path() modifies the path
- req\_url\_path\_append() adds to the path

**Usage**

```
req_url(req, url)

req_url_query(req, ...)

req_url_path(req, ...)

req_url_path_append(req, ...)
```

**Arguments**

req	A <a href="#">request</a> .
url	New URL; completely replaces existing.
...	For req_url_query(): Name-value pairs that provide query parameters. Each value must be either length-1 atomic vector or NULL (which is automatically dropped). For req_url_path() and req_url_path_append(): A sequence of path components that will be combined with /.

**Value**

A modified HTTP [request](#).

**Examples**

```
req <- request("http://example.com")

# Change url components
req %>%
  req_url_path_append("a") %>%
  req_url_path_append("b") %>%
  req_url_path_append("search.html") %>%
  req_url_query(q = "the cool ice")

# Change complete url
req %>%
  req_url("http://google.com")
```

---

req_user_agent	<i>Set user-agent for a request</i>
----------------	-------------------------------------

---

**Description**

This overrides the default user-agent set by httr2 which includes the version numbers of httr2, the curl package, and libcurl.

**Usage**

```
req_user_agent(req, string = NULL)
```

**Arguments**

req	A <a href="#">request</a> .
string	String to be sent in the User-Agent header. If NULL, will user default.

**Value**

A modified HTTP [request](#).

**Examples**

```
# Default user-agent:
request("http://example.com") %>% req_dry_run()

request("http://example.com") %>% req_user_agent("MyString") %>% req_dry_run()

# If you're wrapping in an API in a package, it's polite to set the
# user agent to identify your package.
request("http://example.com") %>%
  req_user_agent("MyPackage (http://mypackage.com)") %>%
  req_dry_run()
```

---

 req\_verbose

*Show extra output when request is performed*

---

### Description

req\_verbose() uses the following prefixes to distinguish between different components of the HTTP requests and responses:

- \* informative curl messages
- <- request headers
- << request body
- -> response headers
- >> response body

### Usage

```
req_verbose(
  req,
  header_req = TRUE,
  header_resp = TRUE,
  body_req = FALSE,
  body_resp = FALSE,
  info = FALSE,
  redact_headers = TRUE
)
```

### Arguments

req	A <a href="#">request</a> .
header_req, header_resp	Show request/response headers?
body_req, body_resp	Should request/response bodies? When the response body is compressed, this will show the number of bytes received in each "chunk".
info	Show informational text from curl? This is mainly useful for debugging https and auth problems, so is disabled by default.
redact_headers	Redact confidential data in the headers? Currently redacts the contents of the Authorization header to prevent you from accidentally leaking credentials when debugging/reprexing.

### Value

A modified HTTP [request](#).

## See Also

[req\\_perform\(\)](#) which exposes a limited subset of these options through the `verbosity` argument and [with\\_verbosity\(\)](#) which allows you to control the verbosity of requests deeper within the call stack.

## Examples

```
# Use `req_verbose()` to see the headers that are sent back and forth when
# making a request
resp <- request("https://httr2.r-lib.org") %>%
  req_verbose() %>%
  req_perform()

# Or use one of the convenient shortcuts:
resp <- request("https://httr2.r-lib.org") %>%
  req_perform(verbosity = 1)
```

---

resp_body_raw	<i>Extract body from response</i>
---------------	-----------------------------------

---

## Description

- `resp_body_raw()` returns the raw bytes.
- `resp_body_string()` returns a UTF-8 string.
- `resp_body_json()` returns parsed JSON.
- `resp_body_html()` returns parsed HTML.
- `resp_body_xml()` returns parsed XML.

`resp_body_json()` and `resp_body_xml()` check that the content-type header is correct; if the server returns an incorrect type you can suppress the check with `check_type = FALSE`.

## Usage

```
resp_body_raw(resp)

resp_body_string(resp, encoding = NULL)

resp_body_json(resp, check_type = TRUE, simplifyVector = FALSE, ...)

resp_body_html(resp, check_type = TRUE, ...)

resp_body_xml(resp, check_type = TRUE, ...)
```

**Arguments**

resp	A response object.
encoding	Character encoding of the body text. If not specified, will use the encoding specified by the content-type, falling back to UTF-8 with a warning if it cannot be found. The resulting string is always re-encoded to UTF-8.
check_type	Check that response has expected content type? Set to FALSE to suppress the automated check
simplifyVector	Should JSON arrays containing only primitives (i.e. booleans, numbers, and strings) be caused to atomic vectors?
...	Other arguments passed on to <code>jsonlite::fromJSON()</code> and <code>xml2::read_xml()</code> respectively.

**Value**

- `resp_body_raw()` returns a raw vector.
- `resp_body_string()` returns a string.
- `resp_body_json()` returns NULL, an atomic vector, or list.
- `resp_body_html()` and `resp_body_xml()` return an `xml2::xml_document`

**Examples**

```

resp <- request("https://httr2.r-lib.org") %>% req_perform()
resp

resp %>% resp_body_raw()
resp %>% resp_body_string()

if (requireNamespace("xml2", quietly = TRUE)) {
  resp %>% resp_body_html()
}

```

---

resp_content_type	<i>Extract response content type and encoding</i>
-------------------	---

---

**Description**

`resp_content_type()` returns the just the type and subtype of the from the Content-Type header. If Content-Type is not provided; it returns NA. Used by `resp_body_json()`, `resp_body_html()`, and `resp_body_xml()`.

`resp_encoding()` returns the likely character encoding of text types, as parsed from the charset parameter of the Content-Type header. If that header is not found, not valid, or no charset parameter is found, returns UTF-8. Used by `resp_body_string()`.

**Usage**

```
resp_content_type(resp)
```

```
resp_encoding(resp)
```

**Arguments**

resp                    An HTTP response object, as created by [req\\_perform\(\)](#).

**Value**

A string. If no content type is specified `resp_content_type()` will return a character NA; if no encoding is specified, `resp_encoding()` will return "UTF-8".

**Examples**

```
resp <- response(header = "Content-type: text/html; charset=utf-8")
resp %>% resp_content_type()
resp %>% resp_encoding()

# No Content-Type header
resp <- response()
resp %>% resp_content_type()
resp %>% resp_encoding()
```

---

resp_date	<i>Extract request date from response</i>
-----------	---

---

**Description**

All responses contain a request date in the Date header; if not provided by the server will be automatically added by `httr2`.

**Usage**

```
resp_date(resp)
```

**Arguments**

resp                    An HTTP response object, as created by [req\\_perform\(\)](#).

**Value**

A POSIXct date-time.

## Examples

```
resp <- response(headers = "Date: Wed, 01 Jan 2020 09:23:15 UTC")
resp %>% resp_date()

# If server doesn't add header (unusual), you get the time the request
# was created:
resp <- response()
resp %>% resp_date()
```

---

resp_headers	<i>Extract headers from a response</i>
--------------	--

---

## Description

- `resp_headers()` retrieves a list of all headers.
- `resp_header()` retrieves a single header.
- `resp_header_exists()` checks if a header is present.

## Usage

```
resp_headers(resp, filter = NULL)
```

```
resp_header(resp, header)
```

```
resp_header_exists(resp, header)
```

## Arguments

resp	An HTTP response object, as created by <code>req_perform()</code> .
filter	A regular expression used to filter the header names. NULL, the default, returns all headers.
header	Header name (case insensitive)

## Value

- `resp_headers()` returns a list.
- `resp_header()` returns a string if the header exists and NULL otherwise.
- `resp_header_exists()` returns TRUE or FALSE.

**Examples**

```

resp <- request("https://httr2.r-lib.org") %>% req_perform()
resp %>% resp_headers()
resp %>% resp_headers("x-")

resp %>% resp_header_exists("server")
resp %>% resp_header("server")
# Headers are case insensitive
resp %>% resp_header("SERVER")

# Returns NULL if header doesn't exist
resp %>% resp_header("this-header-doesnt-exist")

```

---

resp_link_url	<i>Parse link URL from a response</i>
---------------	---------------------------------------

---

**Description**

Parses URLs out of the the Link header as defined by [rfc8288](#).

**Usage**

```
resp_link_url(resp, rel)
```

**Arguments**

**resp** An HTTP response object, as created by [req\\_perform\(\)](#).  
**rel** The "link relation type" value for which to retrieve a URL.

**Value**

Either a string providing a URL, if the specified `rel` exists, or NULL if not.

**Examples**

```

# Simulate response from GitHub code search
resp <- response(headers = paste0("Link: ",
  '<https://api.github.com/search/code?q=addClass+user%3Amozilla&page=2>; rel="next"',
  '<https://api.github.com/search/code?q=addClass+user%3Amozilla&page=34>; rel="last"'
))

resp_link_url(resp, "next")
resp_link_url(resp, "last")
resp_link_url(resp, "prev")

```

---

resp_raw	<i>Show the raw response</i>
----------	------------------------------

---

### Description

This function reconstructs the HTTP message that httr2 received from the server. It's unlikely to be exactly byte-for-byte identical (because most servers compress at least the body, and HTTP/2 can also compress the headers), but it conveys the same information.

### Usage

```
resp_raw(resp)
```

### Arguments

resp            An HTTP [response](#)

### Value

resp (invisibly).

### Examples

```
resp <- request("https://httpbin.org/json") %>% req_perform()
resp %>% resp_raw()
```

---

resp_retry_after	<i>Extract wait time from a response</i>
------------------	--

---

### Description

Computes how many seconds you should wait before retrying a request by inspecting the `Retry-After` header. It parses both forms (absolute and relative) and returns the number of seconds to wait. If the heading is not found, it will return NA.

### Usage

```
resp_retry_after(resp)
```

### Arguments

resp            An HTTP response object, as created by [req\\_perform\(\)](#).

### Value

Scalar double giving the number of seconds to wait before retrying a request.

## Examples

```
resp <- response(headers = "Retry-After: 30")
resp %>% resp_retry_after()

resp <- response(headers = "Retry-After: Mon, 20 Sep 2025 21:44:05 UTC")
resp %>% resp_retry_after()
```

---

resp\_status

*Extract HTTP status from response*

---

## Description

- `resp_status()` retrieves the numeric HTTP status code
- `resp_status_desc()` retrieves the brief textual description.
- `resp_is_error()` returns TRUE if the status code represents an error (i.e. a 4xx or 5xx status).
- `resp_check_status()` turns HTTPs errors into R errors.

These functions are mostly for internal use because in most cases you will only ever see a 200 response:

- 1xx are handled internally by curl.
- 3xx redirects are automatically followed. You will only see them if you have deliberately suppressed redirects with `req %>% req_options(followlocation = FALSE)`.
- 4xx client and 5xx server errors are automatically turned into R errors. You can stop them from being turned into R errors with `req_error()`, e.g. `req %>% req_error(is_error = ~FALSE)`.

## Usage

```
resp_status(resp)

resp_status_desc(resp)

resp_is_error(resp)

resp_check_status(resp, info = NULL)
```

## Arguments

`resp` An HTTP response object, as created by `req_perform()`.

`info` A character vector of additional information to include in the error message. Passed to `rlang::abort()`.

**Value**

- `resp_status()` returns a scalar integer
- `resp_status_desc()` returns a string
- `resp_is_error()` returns TRUE or FALSE
- `resp_check_status()` invisibly returns the response if it's ok; otherwise it throws an error with class `httr2_http_{status}`.

**Examples**

```
# An HTTP status code you're unlikely to see in the wild:
resp <- response(418)
resp %>% resp_is_error()
resp %>% resp_status()
resp %>% resp_status_desc()
```

---

secrets

*Secret management*

---

**Description**

`httr2` provides a handful of functions designed for working with confidential data. These are useful because testing packages that use `httr2` often requires some confidential data that needs to be available for testing, but should not be available to package users.

- `secret_encrypt()` and `secret_decrypt()` work with individual strings
- `secret_write_rds()` and `secret_read_rds()` work with `.rds` files
- `secret_make_key()` generates a random string to use as a key.
- `secret_has_key()` returns TRUE if the key is available; you can use it in examples and vignettes that you want to evaluate on your CI, but not for CRAN/package users.

These all look for the key in an environment variable. When used inside of `testthat`, they will automatically `testthat::skip()` the test if the env var isn't found. (Outside of `testthat`, they'll error if the env var isn't found.)

**Usage**

```
secret_make_key()
```

```
secret_encrypt(x, key)
```

```
secret_decrypt(encrypted, key)
```

```
secret_write_rds(x, path, key)
```

```
secret_read_rds(path, key)
```

```
secret_has_key(key)
```

**Arguments**

x	Object to encrypt. Must be a string for <code>secret_encrypt()</code> .
key	Encryption key; this is the password that allows you to "lock" and "unlock" the secret. The easiest way to specify this is as the name of an environment variable. Alternatively, if you already have a base64url encoded string, you can wrap it in <code>I()</code> , or you can pass the raw vector in directly.
encrypted	String to decrypt
path	Path to <code>.rds</code> file

**Value**

- `secret_decrypt()` and `secret_encrypt()` return strings.
- `secret_write_rds()` returns `x` invisibly; `secret_read_rds()` returns the saved object.
- `secret_make_key()` returns a string with class `AsIs`.
- `secret_has_key()` returns `TRUE` or `FALSE`.

**Basic workflow**

1. Use `secret_make_key()` to generate a password. Make this available as an env var (e.g. `{MYPACKAGE}_KEY`) by adding a line to your `.Renviron`.
2. Encrypt strings with `secret_encrypt()` and other data with `secret_write_rds()`, setting `key = "{MYPACKAGE}_KEY"`.
3. In your tests, decrypt the data with `secret_decrypt()` or `secret_read_rds()` to match how you encrypt it.
4. If you push this code to your CI server, it will already "work" because all functions automatically skip tests when your `{MYPACKAGE}_KEY` env var isn't set. To make the tests actually run, you'll need to set the env var using whatever tool your CI system provides for setting env vars. Make sure to carefully inspect the test output to check that the skips have actually gone away.

**Examples**

```
key <- secret_make_key()

path <- tempfile()
secret_write_rds(mtcars, path, key = key)
secret_read_rds(path, key)

# While you can manage the key explicitly in a variable, it's much
# easier to store in an environment variable. In real life, you should
# NEVER use `Sys.setenv()` to create this env var because you will
# also store the secret in your `.Rhistory`. Instead add it to your
# .Renviron using `usethis::edit_r_environ()` or similar.
Sys.setenv("MY_KEY" = key)

x <- secret_encrypt("This is a secret", "MY_KEY")
x
secret_decrypt(x, "MY_KEY")
```

---

url_parse	<i>Parse and build URLs</i>
-----------	-----------------------------

---

### Description

url\_parse() parses a URL into its component pieces; url\_build() does the reverse, converting a list of pieces into a string URL. See [rfc3986](#) for details of parsing algorithm.

### Usage

```
url_parse(url)
```

```
url_build(url)
```

### Arguments

url For url\_parse() a string to parse into a URL; for url\_build() a URL to turn back into a string.

### Value

- url\_build() returns a string.
- url\_parse() returns a URL: a S3 list with class httr2\_url and elements scheme, hostname, port, path, fragment, query, username, password.

### Examples

```
url_parse("http://google.com/")
url_parse("http://google.com:80/")
url_parse("http://google.com:80/?a=1&b=2")
url_parse("http://username@google.com:80/path;test?a=1&b=2#40")

url <- url_parse("http://google.com/")
url$port <- 80
url$hostname <- "example.com"
url$query <- list(a = 1, b = 2, c = 3)
url_build(url)
```

---

with_mock	<i>Temporarily mock requests</i>
-----------	----------------------------------

---

### Description

Mocking allows you to selectively and temporarily replace the response you would typically receive from a request with your own code. It's primarily used for testing.

**Usage**

```
with_mock(mock, code)

local_mock(mock, env = caller_env())
```

**Arguments**

mock	A single argument function called with a request object. It should return either NULL (if it doesn't want to handle the request) or a <a href="#">response</a> (if it does).
code	Code to execute in the temporary environment.
env	Environment to use for scoping changes.

**Value**

with\_mock() returns the result of evaluating code.

**Examples**

```
# This function should perform a response against google.com:
google <- function() {
  request("http://google.com") %>%
  req_perform()
}

# But I can use a mock to instead return my own made up response:
my_mock <- function(req) {
  response(status_code = 403)
}
with_mock(my_mock, google())
```

---

with_verbosity	<i>Temporarily set verbosity for all requests</i>
----------------	---

---

**Description**

with\_verbosity() is useful for debugging httr2 code buried deep inside another package because it allows you to see exactly what's been sent and requested.

**Usage**

```
with_verbosity(code, verbosity = 1)
```

**Arguments**

<code>code</code>	Code to execute
<code>verbosity</code>	How much information to print? This is a wrapper around <code>req_verbose()</code> that uses an integer to control verbosity: <ul style="list-style-type: none"><li>• 0: no output</li><li>• 1: show headers</li><li>• 2: show headers and bodies</li><li>• 3: show headers, bodies, and curl status messages.</li></ul>

**Value**

The result of evaluating code.

**Examples**

```
fun <- function() {  
  request("https://httr2.r-lib.org") %>% req_perform()  
}  
with_verbosity(fun())
```
